Abstract
Line-to-line-to-line unsymmetrical faults either involving or not involving ground are in the classical fault analysis approach difficult to analyse. This is because the classical solution requires use of the knowledge of connection of symmetrical component sequence networks for various common faults. In this approach, the phase fault constraints are converted into symmetrical sequence constraints and the sequence networks connected in a way that satisfies the constraints. The symmetrical component constraints for an unsymmetrical three-phase fault not involving ground do not lend themselves easy to the connection of the sequence networks. The exception is that, because the phase currents at the fault summate to zero, the zero sequence current is zero and therefore the zero sequence network is not connected. The connection of the positive and negative sequence networks is difficult to deduce when the fault is unsymmetrical. A classical solution is therefore difficult to find. In contrast, a solution by the general method of fault admittance matrix does not require prior knowledge of how the sequence networks are connected. It is therefore more versatile than the classical methods. The paper presents a procedure for solving a three-phase unsymmetrical fault, with different fault impedances, hence fault admittances in each phase. A computer program based on the general fault admittance method is developed and used to analyse an unsymmetrical three-phase fault on a simple power system with a delta-earthed-star connected transformer.

Keywords: Unbalanced faults analysis, Line-to-line-to-line unsymmetrical fault, Fault admittance matrix, Delta-earthed-star transformer.

1. Introduction
The paper presents a method for solving an unsymmetrical line-to-line-to-line fault using the general fault impedance method. The general fault admittance method differs from the classical approaches based on symmetrical components...
Nomenclatures

- $I_{fpj}$: Phase current in the faulted bus bar $j$
- $I_{fsj}$: Symmetrical component current at the faulted bus bar $j$
- $V_{fs1}$: Symmetrical component voltage at the faulted bus bar $1$
- $Y_{af}$: Phase $a$ fault admittance
- $Y_{bf}$: Phase $b$ fault admittance
- $Y_{cf}$: Phase $c$ fault admittance
- $Y_{fs}$: Symmetrical fault admittance
- $Y_{gf}$: Ground fault admittance

Greek Symbols

- $\alpha$: Complex operator $1\angle 120^\circ$

Since it does not require prior knowledge of how the sequence components of currents and voltages are related [1-7]. In the classical approach, knowledge of how the sequence components are related is required because the sequence networks must be connected in a prescribed way for a particular fault. Then the sequence currents and voltages at the fault are determined, after which symmetrical component currents and voltages in the rest of the network are calculated. Phase currents and voltages are found by transforming the respective symmetrical component values [8-11].

The fault admittance method is general in the sense that any fault impedances can be represented, provided the special case of a zero impedance fault is catered for. This paper discusses a procedure for simulating and solving an unsymmetrical line-to-line-to-line fault.

2. Background

A line-to-line-to-line fault presents low value impedances, with zero values for direct short circuits or metallic faults, between the three phases at the point of a fault in the network. In general, a fault may be represented as shown in Fig. 1.

In Fig. 1, a fault at a bus bar is represented by fault admittances in each phase, i.e., the inverse of the fault impedance in the phase, and the admittance in the ground path. Note that the fault admittance for a short-circuited phase is represented by an infinite value, while that for an open-circuited phase is a zero value. In a line-to-line-to-line fault the fault is between all the three phases; $a$, $b$ and $c$. Thus for a line-to-line-to-line fault the admittance $Y_{gf}$ is zero while the admittances $Y_{af}$, $Y_{bf}$ and $Y_{cf}$ are the inverses of the fault impedances in the respective phases.

A systematic approach for using a fault admittance matrix in the general fault admittance method is given by Sakala and Daka [1-7]. The method is based on the work by Elgerd [8] details of which are summarized in Appendix A.

3. Line-to-Line-to-Line Unsymmetrical Fault Simulation

The symmetrical component fault admittance matrix for a general fault admittance matrix when the ground is not involved, i.e., $Y_{gf}$ is zero, reduces to (Appendix A):

Journal of Engineering Science and Technology  September 2015, Vol. 10(9)
The values $Y_{af}$, $Y_{bf}$ and $Y_{cf}$ are the fault admittances in the faulted phases. The impedances required to simulate the line-to-line-to-line unsymmetrical fault in general terms are the impedances in the faulted phases. In the current work, the fault impedances are as follows: in the $a$ phase zero, in the $b$ phase $j0.1$ and $j0.2$ in the $c$ phase. Furthermore, since $Y_{af}$ is infinite the symmetrical component fault admittance matrix becomes:

$$Y = \begin{bmatrix} Y_a + Y_f & -(a^2 Y_a + a Y_f) & 0 \\ -a^2 Y_a + a Y_f & Y_a + Y_f & 0 \\ 0 & 0 & 0 \end{bmatrix}$$  \hspace{1cm} (2)$$

The symmetrical component fault admittance matrix may be substituted in Eq. (A-4) in Appendix A to obtain a simplified value of $I_{fsj}$ as:

$$I_{fsj} = \frac{V^0_{fsj}}{1 + [Y_a + Y_f (Z_{aw} + Z_{aw}) + 3Z_{aw} Z_{aw} Y_{af}]^{-1} \begin{bmatrix} Y_a + Y_f + 3Z_{aw} Y_{fsj} \\ -a^2 Y_{fsj} - a Y_f \\ 0 \end{bmatrix}}$$  \hspace{1cm} (3)$$

The simplified expression is useful for validating the results from the computer program.

Equations (1) to (3) form the basis of a computer simulation program to solve unbalanced faults for a general power system using the fault admittance matrix method. The program is applied on a power system comprising of three bus bars to solve for a line-to-line-to-line unsymmetrical fault.

Figure 2 shows a simple three bus bar power system with one generator, one transformer and one transmission line. The system is configured based on the simple power system that Saadat uses [9].
The power system per unit data is given in Table 1, where the subscripts 1, 2, and 0 refer to the positive, negative and zero sequence values respectively. The neutral point of the generator is grounded through zero impedance.

The transformer windings are delta connected on the low voltage side and earthed-star connected on the high voltage side, with the neutral solidly grounded. The phase shift of the transformer is 30˚, i.e., from the generator side to the line side. Figure 3 shows the transformer voltages for a Yd11 connection which has a 30˚ phase shift.

The computer program incorporates an input program that calculates the sequence admittance and impedance matrices and then assembles the symmetrical component bus impedance matrix for the power system. The symmetrical component bus impedance incorporates all the sequences values and has $3n$ rows and $3n$ columns where $n$ is the number of bus bars. In general, the mutual terms between sequence values are zero as a three-phase power system is, by design, balanced.

The power system is assumed to be at no load before the occurrence of a fault. In practice, the pre-fault conditions, established by a load flow study may be used.
For developing a computer program the assumption of no load, and therefore voltages of 1.0 per unit at the bus bars and in the generator, is adequate.

The line-to-line-to-line unsymmetrical fault is at bus bar 1, the load bus bar. The line-to-line-to-line unsymmetrical fault is described by the impedances in the respective phases, i.e., \( 0 \, \Omega, j0.1 \, \Omega \) and \( j0.2 \, \Omega \) in the \( a, b \) and \( c \) phases respectively.

The presence of the delta earthed-star transformer poses a challenge in terms of its modelling. In the computer program, the transformer is modelled in one of two ways; as a normal star-star connection, for the positive and negative sequence networks or as a delta-star transformer with a phase shift. In the former model, the phase shifts are incorporated when assembling the sequence currents to obtain the phase values.

In particular, on the delta-connected side of the transformer the positive sequence currents’ angles are increased by the phase shift while the angle of the negative sequence currents are reduced by the same value. The zero sequence currents, if any, are not affected by the phase shifts.

Both models for the delta star transformer give same results. The \( \sqrt{3} \) line current factor is used to find the line currents on the delta side of the delta star transformer.

5. Results and Discussions

A summary of results obtained from a computer simulation of the power system as given in Section 4 are presented in this section. Further results details are provided Appendix B.

5.1. Symmetrical component impedances at the faulted bus bar

The Thevenin’s self-sequence impedances of the network seen from the faulted bus bar are:

\[
\begin{bmatrix}
  j0.5 & 0 & 0 \\
  0 & j0.5 & 0 \\
  0 & 0 & j0.8125
\end{bmatrix}
\]  
(4)

The connection of the sequence networks for the line-to-line-to-line unsymmetrical fault is not required to perform the study by the general fault admittance method. The phase and symmetrical component fault matrices are found in the course of the study and the latter is part of the output results shown in Appendix B, Table B.1.

5.2. Symmetrical fault admittance matrix

The symmetrical component fault admittance matrix obtained from the program for the line-to-line-to-line unsymmetrical fault shown in Eq. (5) is in agreement with the theoretical value, obtained using Eq. (2).

\[
\begin{bmatrix}
  -j15 & 4.3301 - j7.5 & 0 \\
  -4.3301 - j7.5 & -j15 & 0 \\
  0 & 0 & 0
\end{bmatrix}
\]  
(5)
5.3. Sequence fault currents

The symmetrical component fault currents (Positive, negative and zero sequences) at the fault points are equal to the values obtained using Eq. (3):

\[
I_{fs} = \begin{bmatrix}
1.6822 \angle -90^\circ \\
0.1619 \angle -60^\circ \\
0
\end{bmatrix}
\] (6)

Note that the zero sequence current in Eq. (6) is zero, which is consistent with theory.

5.4. Phase fault currents

The phase currents in the fault are given by:

\[
I_{fp} = \begin{bmatrix}
1.8242 \angle -87.5^\circ \\
1.6900 \angle 144.5^\circ \\
1.5244 \angle 33.0^\circ 
\end{bmatrix}
\] (7)

Note that the currents in Eq. (7) summate to zero as there is no current flowing into the ground from the fault.

The phase fault currents are highest in the phase \(a\), the phase with the least fault impedance. The next largest current is phase \(b\), which had the second lowest fault impedance. Phase \(c\), with the largest fault impedance has the least fault current.

Figure 4 shows the transformer and transmission line phase currents. The phase currents in the transmission line are equal to the currents in the fault. Note that the current at the receiving end of the line is by convention considered as flowing into the line, rather than out of it.

The currents on the line side are equal to the currents in the line, after allowing for the sign change due to convention. The currents in the transformer windings satisfy the ampere-turn balance requirements of the transformer. The magnitudes of the currents at the sending end of the transformer, the delta connected side, are \(\sqrt{3}\) times the magnitudes of the currents in the phase windings, although not a phase-to-phase correspondence. While the magnitude in phase \(a\) on the delta connected side is \(\sqrt{3}\) times the current magnitude on the star connected side, the magnitude in the \(b\) phase on the delta connected side is \(\sqrt{3}\) times the value of the current magnitude in the \(c\) phase.

Similarly the magnitude of the current in the \(c\) phase on the delta connected side is \(\sqrt{3}\) times the current magnitude in the \(b\) phase. The phase fault currents flowing from the generator are equal to the phase currents into the transformer.

5.5. Fault voltages

The symmetrical component voltages at the fault point are given in Eq. (8). They show that the zero sequence voltage is zero, which is consistent with theory. The positive and negative sequence voltages are not equal.

\[
V_{fs} = \begin{bmatrix}
0.1589 \angle 0^\circ \\
0.0809 \angle 210^\circ \\
0
\end{bmatrix}
\] (8)
The phase voltages at the bus bars are given in Table 2. The voltages at bus bar 1 are the voltages at the fault point. The phase voltages at the fault are lowest in phase \( a \), which has the lowest fault impedance, followed by that in phase \( b \), with the next lowest fault impedance.

The phase voltages at bus bar 2 are nearly equal being 54.5%, 58.1% and 61.5% of the prefault values in the \( a \), \( b \) and \( c \) phases respectively.

The phase voltages at bus bar 3 are nearly balanced with magnitudes of 72.7%, 76.8% and 74.6% of the prefault values in the \( a \), \( b \) and \( c \) phases respectively. The phase voltages at bus bar 3 lead the phase voltages at bus bar 2 by 33.1°, 26.9° and 30.0° in the \( a \), \( b \) and \( c \) phases respectively.

### 5.6. Future work

The work presented in this paper has shown that a line-to-line-to-line unsymmetrical fault can be solved using the general fault admittance method provided a small enough impedance is used to simulate a zero impedance fault. In future work the unsymmetrical fault will be rotated around the phases to demonstrate the versatility of the method. That is the fault impedances of 0 \( \Omega \), \( j0.1 \Omega \) and \( j0.2 \Omega \) will be in phases \( b \), \( c \) and \( a \) respectively for one study and in
phases $c$, $a$ and $b$ respectively for another study. The method will also be applied to solve various faults on a practical system.

6. Conclusions

A line-to-line-to-line unsymmetrical fault has been solved using the general fault admittance method. This type of fault is difficult to solve using the classical symmetrical components approach based on the connection of the sequence component networks at the fault point. The difficulty arises because the phase and symmetrical component constraints do not lead to suggest a simple connection of the sequence component networks.

The results show that the phase voltages on the delta side of a delta earthed star connected transformer, with the fault on the star side, are nearly balanced. This effect is consistent with the effect that a delta star connected transformer has on unbalanced loads on the star side.

The line-to-line-to-line unsymmetrical fault is interesting for studying the delta earthed star transformer arrangement. The currents and voltages are nearly balanced on both sides of the transformer. Phase shifts of nearly 30° between the voltages on the delta side to those on the star connected side are shown, which is consistent with theory. The results give an insight in the effect that a delta earthed star transformer has on a power system during line-to-line-to-line unsymmetrical faults.

The main advantage of the general fault admittance method is that the user is not required to know beforehand how the sequence networks should be connected at the fault point in order to obtain the sequence currents and voltages. The user can deduce the various relationships from the results. The method is therefore easier to use and teach than the classical approach in which each network is solved in isolation and then the results combined to obtain the phase quantities.

Appendix A

General Fault Admittance Matrix Method for Line-to-line-to-Line Unsymmetrical Fault

The general fault admittance matrix is given by:

\[
Y_{f} = \begin{bmatrix}
1 & Y_{gf} & Y_{gf} \\
Y_{gf} & Y_{ff} & Y_{gf} \\
Y_{gf} & Y_{gf} & Y_{ff}
\end{bmatrix}
\]

Equation (A-1)

The general expression [1-8] for \( Y_{f} \) is given by:

\[
Y_{f} = \begin{bmatrix}
Y_{\mu11} & Y_{\mu12} & Y_{\mu13} \\
Y_{\mu21} & Y_{\mu22} & Y_{\mu23} \\
Y_{\mu31} & Y_{\mu32} & Y_{\mu33}
\end{bmatrix}
\]

where

\[
Y_{\mu11} = Y_{\mu22} = \frac{1}{3} Y_{gf} (Y_{gf} + Y_{gf} + Y_{gf}) + Y_{gf} Y_{gf} + Y_{gf} Y_{gf} \\
Y_{\mu13} = \frac{1}{3} Y_{gf} (Y_{gf} + Y_{gf} + Y_{gf}) \\
Y_{\mu12} = \frac{1}{3} Y_{gf} (Y_{gf} + \alpha Y_{gf} + \alpha Y_{gf}) - (Y_{gf} Y_{gf} + \alpha Y_{gf} Y_{gf} + \alpha^2 Y_{gf} Y_{gf})
\]
The above expressions simplify considerably depending on the type of fault.

A.1. Currents in the fault

At the faulted bus bar, say bus bar \( j \), the symmetrical component currents in the fault are given by:

\[
I_{pj} = Y_p (U + Z_{pj} Y_p)^{-1} V_{pj}^0
\]  

(A-3)

where \( U \) is the unit matrix:

\[
U = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

and \( Z_{pj} \) is the \( j^{th} \) component of the symmetrical component bus impedance matrix

\[
Z_{pj} = \begin{bmatrix}
Z_{pj+} & 0 & 0 \\
0 & Z_{pj-} & 0 \\
0 & 0 & Z_{p0j}
\end{bmatrix}
\]

The element \( Z_{pj+} \) is the Thevenin’s positive sequence impedance at the faulted bus bar, \( Z_{pj-} \) is the Thevenin’s negative sequence impedance at the faulted bus bar, and \( Z_{p0j} \) is the Thevenin’s zero sequence impedance at the faulted bus bar. Note that as the network is balanced the mutual terms are all zero.

In Eq. (4) \( V_{pj}^0 \) is the pre-fault symmetrical component voltage at bus bar \( j \) the faulted bus bar:

\[
V_{pj}^0 = \begin{bmatrix}
V_{pj+}^0 \\
V_{pj-}^0 \\
V_{p0j}^0
\end{bmatrix} = \begin{bmatrix}
V_+ \\
0 \\
0
\end{bmatrix}
\]

where \( V_+ \) is the positive sequence voltage before the fault. The negative and zero sequence voltages are zero because the system is balanced prior to the fault.

The phase currents in the fault are then obtained by transformation:

\[
I_{pj} = \begin{bmatrix}
I_{pj+} \\
I_{pj-} \\
I_{p0j}
\end{bmatrix} = TI_{pj}
\]  

(A-4)

A.2. Voltages at the bus bars

The symmetrical component voltage at the faulted bus bar \( j \) is given by:
The symmetrical component voltage at a bus bar $i$ for a fault at bus bar $j$ is given by:

$$V_{i0} = V_{i-} = (U + Z_{sij} Y_{ij}^{-1}) V_{q0}$$  \hspace{1cm} (A-5)$$

The symmetrical component voltage at a bus bar $i$ for a fault at bus bar $j$ is given by:

$$V_{i0} = V_{i-} = (U + Z_{sij} Y_{ij}^{-1}) V_{q0}$$  \hspace{1cm} (A-7)$$

$$V_{i0} = \begin{bmatrix} V_{i0}^+ \\ V_{i0}^- \\ V_{i0}^0 \end{bmatrix}$$

$$V_{i0} = \begin{bmatrix} V_{i0}^+ - Z_{sij} Y_{ij} (U + Z_{sij} Y_{ij}) V_{q0}^0 \end{bmatrix}$$

where \(V_{i0}^0\) gives the symmetrical component pre-fault voltages at bus bar $i$.

The negative and zero sequence pre-fault voltages are zero.

In Eq. (A-6), $Z_{sij}$ gives the $ij^{th}$ components of the symmetrical component bus impedance matrix, the mutual terms for row $i$ and column $j$ (corresponding to bus bars $i$ and $j$)

$$Z_{sij} = \begin{bmatrix} Z_{sij}^+ & 0 & 0 \\ 0 & Z_{sij}^- & 0 \\ 0 & 0 & Z_{sij}^0 \end{bmatrix}$$

The phase voltages in the fault, at bus bar $j$, and at bus bar $i$ are then obtained by transformation:

$$V_{ij} = Y_{ij} V_{i0}$$  \hspace{1cm} (A-7)$$

A.3. Currents in lines, transformers and generators

The symmetrical component currents in a line between bus bars $i$ and $j$ are given by:

$$I_{ij} = Y_{ij} (V_{i0} - V_{j0})$$  \hspace{1cm} (A-8)$$

where \(Y_{ij}\) is the symmetrical component admittance of the branch between bus bars $i$ and $j$.

Equation (A-8) also applies to transformers, when there is no phase shift between the terminal quantities or when the phase shift is catered for when assembling the phase quantities. In the latter case, the positive sequence values are phase shifted forward and the negative sequence values are phase shifted backwards by the phase shift (usually $\pm 30^\circ$). The line currents on the delta-connected side of a delta star transformer should have the appropriate phase to line conversion factor.

Equation (A-8) also applies to a generator where the source voltage will be the pre-fault induced voltage and the receiving end bus bar voltage is the post-fault voltages at the bus bar.
The phase currents in the branch are found by transformation:

\[
\begin{bmatrix}
I_{fij} \\
I_{cij} \\
I_{bifj} \\
I_{aifj}
\end{bmatrix} =
T
\begin{bmatrix}
I_{fij} \\
I_{cij} \\
I_{bifj} \\
I_{aifj}
\end{bmatrix}
\tag{A-9}
\]

Equations (A-1) to (A-9) are used in a computer program to solve unbalanced faults.
